

XH4000EX HardWire™ Array Family

Preliminary

Product Specification

Features

- Mask-programmed versions of Programmable Logic Cell Arrays FPGA
 - Specifically designed for easy XC4000EX series FPGA conversions
 - Significant cost reduction for high volume applications
 - Transparent conversion from FPGA device
 - On-chip scan-path test registers
 - High performance CMOS process
 - Meets XC4000EX series -3 speeds
 - Supports all XC4000EX Select-RAM™ features
 - Low voltage versions available for 3.3 V operation
- Easy conversion with guaranteed results
 - No customer engineering resource required
 - Fully pin-for-pin compatible
 - Supports most popular package types
 - Same specifications and architecture as programmable FPGA devices
 - All nets and CLBs preserved
 - FPGA Design File used to generate production ready prototypes
 - Prototypes built on production fab line, fully tested to production specification
 - Greater than 95% fault coverage

Description

The XH4000EX Series HardWire Arrays are advanced mask-programmed versions of the XC4000 programmable devices. In high-volume applications where the design is stable, the programmable FPGA devices used for prototyping and initial production can be replaced by their HardWire Array equivalents. This offers a significant cost reduction with virtually no risk or engineering resources required.

In a programmable FPGA device, the logic functions and interconnections are determined by the configuration program data, loaded and stored in internal static-memory cells. The HardWire device has the identical functional architecture as the programmed FPGA device it replaces. In the HardWire device, the logic is optimized for area but maintains the relative timing relationship.

Xilinx manufactures the HardWire device using the information from the programmed FPGA design file. Since the HardWire device is both pinout and architecturally identical to the programmable FPGA device, it is easily created without all the costly and time-consuming customer engineering activity that other semicustom solutions would require – no redesign time, no expensive and time-consuming simulation runs, no place and route, no test-vector generation. Xilinx proprietary software checks the design and maintains timing relationships as well as automatically generating test vectors. The combination of the program-

HardWire Device	Replacement FPGA	Speed Grade	Packages							
			PQ208	PQ240	PG299	HQ304	BG352	PG411	BG432	PG475

X7090

mable FPGA device and the HardWire Array offers the fastest and easiest way to get a new product to market, while ensuring low cost, low risk, and high-volume cost reduction.

The XH4000EX HardWire technology further optimizes silicon area by removing all unused logic in a CLB, and removing any unused CLBs and routing resources. In fact, all unused FPGA features are eliminated in the XH4000EX. However, using our DesignLock™ technology, the implementation of the CLBs (including placement and routing) are maintained. This unique conversion process also eliminates the need for timing simulation. Timing is guaranteed through our Design Review process with the aid of our proprietary software.

See The Xilinx *Data Book* for more information on the XC4000 architecture.

Interconnect

User-defined interconnect resources in the device provide routing paths to connect inputs and outputs of the I/O and logic blocks into logic networks.

The speed of the interconnect paths of the HardWire Array is significantly faster, since all interconnections are fixed metal connections.

Architectural Enhancements

Compared to older array families, XH4000EX HardWire arrays provide significant enhancements. Powerful system features, as listed below, are incorporated to improve system speed, device flexibility, and ease of use.

- JTAG Boundary Scan IEEE 1149.1 Boundary-scan
- Select-RAM Memory: on chip RAM with:
 - Synchronous write option
 - Dual-port RAM option

STARTUP

The STARTUP User Logic block is completely supported in the XH4000EX. The input pins for GSR and GTS can be tied anywhere in the design. Each of these pins can also be inverted, as in the XC5200 FPGA. Refer to Figure 1 for a detailed block diagram of the STARTUP User Logic block. Xilinx recommends the use of the STARTUP block for FPGA designs. By utilizing the GSR pin, all flip-flops in the design may be cleared. It is further recommended that the GSR input be driven directly from a device pin rather than from internal logic. This permits the design to be fully reset from an external device pin, resulting in greater testability.

Figure 1. STARTUP User Logic Block

Similarly, the GTS pin should also be connected to an external device pin so that the FPGA/HardWire may have all I/O pins at a three-state condition. This condition is often necessary for printed circuit board level manufacturing testing and is therefore a recommended design practice.

Configuration Modes

XC4000E devices have six configuration modes. XH4000EX devices have the same six modes, plus an additional configuration mode. These modes are selected by a 3-bit input code applied to the M2, M1, and M0 inputs. These are three self-loading Master modes, two Peripheral modes, and a Serial Slave mode, which is used primarily for daisy-chain devices. The seventh mode, called Express mode, is an additional slave mode that allows high-speed parallel configuration of the high-capacity XH4000EX devices. The coding for modes selection is shown in Table 1.

Table 1. Configuration Modes

Mode	M2	M1	M0	CCLK	Data
Master Serial	0	0	0	output	Bit-Serial
Slave Serial	1	1	1	input	Bit-Serial
Master Parallel Up	1	0	0	output	Byte-Wide, increment from 00000
Master Parallel Down	1	1	0	output	Byte-Wide, increment from 3FFFF
Peripheral Synchronous*	0	1	1	input	Byte-Wide
Peripheral Asynchronous*	1	0	1	output	Byte-Wide
Express (XC4000EX only)	0	1	0	input	Byte-Wide
Reserved	0	0	1	–	–

Note: * Peripheral Synchronous can be considered byte-wide Slave Parallel

A detailed description of each configuration mode, with timing information, is included in the XC4000E data sheet. For more information on Configuration Emulation, refer to the Design Considerations section of this Data Book.

Power Distribution

Power for the HardWire Array is distributed through a grid to achieve high noise immunity and isolation between logic and I/O. Inside the device, dedicated VCC and ground rings surround the logic array and provide power to the I/O drivers. An independent matrix of VCC and ground lines supplies the interior logic of the device. This power distribution grid provides a stable supply and ground for all internal logic, providing the external package power pins are all connected and appropriately decoupled. Typically a 0.1- μ F capacitor connected near the VCC and ground pins will provide adequate decoupling.

Output buffers capable of driving the specified 12-mA/24-mA loads under worst-case conditions may be capable of driving many times that current in a best case. Noise can be reduced by minimizing external load capacitance and reducing simultaneous output transitions in the same direction. It may also be beneficial to locate heavily loaded output buffers near the ground pads. The I/O Block output buffers

have a slew-limited mode which should be used where output rise and fall times are not speed critical. Slew-limited outputs maintain their dc drive capability, but generate less external reflections and internal noise. A maximum total external capacitive load for simultaneous fast-mode switching in the same direction is 100 pF per power/ground pin pair. For slew-rate limited outputs this total is four times larger.

XC4000EX-Family Pin Assignments

Xilinx offers members of the XH4000EX family in a variety of surface-mount package types, with pin counts from 208 to 304.

Each chip is offered in several package types to accommodate the available PC-board space and manufacturing technology. Most package types are also offered with different chips to accommodate design changes without requiring PC-board changes.

Dedicated or Special Pins on XH4000EX HardWire Array

Pin Function		
Pin Name	Configuration Emulation Mode	
	During Configuration	During Operation
M0	M0	User Input ^(1,2)
M1	M1	User Output ^(1,2)
M2	M2	User Input ^(1,2)
CCLK	Master: Output, Slave: Input	HIGH - Internal Pull-up
PROGRAM	PROGRAM Input	Global Reset Device - "Reconfigure"
DONE	DONE Output	HIGH - Internal Pull-up
HDC	HDC Output	User I/O
LDC	LDC Output	User I/O
INIT	Master: INIT Input, Slave POR Output	Open Drain
DIN	DIN Pin	User I/O
DOUT	DOUT Pin	User I/O

Notes:

1. User Pin is only accessible through special schematic I/O Macros
2. Pin does not have an associated IOB register(s)

X7110

Unrestricted User-Programmable I/O Pins.

An I/O pin may be programmed by the user to be an Input or an Output pin following configuration. Before configuration is completed, these pins have an internal high-value pull-up resistor that defines the logic level as High.

Production Test Methodology

The Xilinx XH4000EX utilizes a Production Test Methodology which permits total testability of all testable faults. This is achieved through high fault coverage vectors generated by an Automatic Test Vector Generator (ATPG). The vectors are fed via both a serial and a parallel data path for the highest degree of fault observation.

One major advantage of Xilinx's test methodology is that the customer is not required to generate any production test vectors. Since this can often consume a great deal of time, Xilinx HardWire can save valuable customer engineering resources.

The user flip-flops in the design are converted into scannable elements. All flip-flops in the dedicated logic such as Configuration Emulation or Boundary Scan are also converted into scannable elements. These elements are then combined to

form full-scan chains. Up to eight chains are used in order to reduce the total required test time. By using a combination of random and deterministic fault algorithms, high fault coverage is achieved resulting in total testability of all testable faults.

ESD Considerations

The XC5400 has similar ESD protection as the XC5200 FPGA, and is able to withstand ESD up to 2,000 volts. The HardWire is manufactured in CMOS process technology, and appropriate Electro-Static Discharge (ESD) handling precautions should be followed.

3 V/5 V Considerations

The XC5400 HardWire Array can operate either as 5 volt only, or as a 3.3 volt device (part number XC4400L).

XH4000EX	5 Volt Operation				3.3 Volt Operation			
	V _{IL} (max)	V _{IH} (min)	V _{OL} (max)	V _{OH} (min)	V _{IL} (max)	V _{IH} (min)	V _{OL} (max)	V _{OH} (min)
	0.80	2.00	0.40	V _{CC} - 0.4	0.80	2.20	0.30	V _{CC} - 0.3
